Coherent Electron Cooling

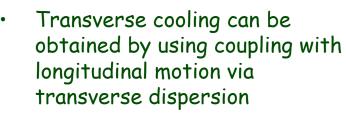

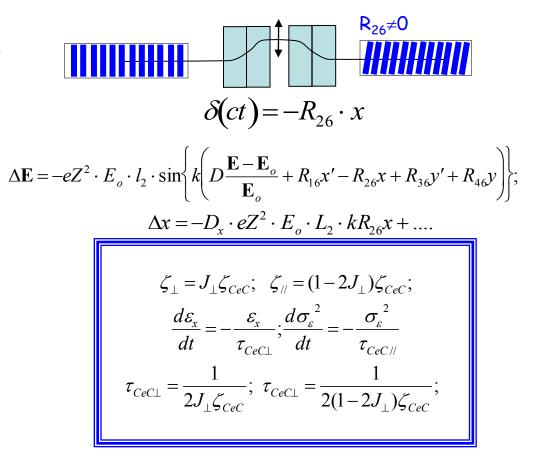

Transverse cooling

- Sharing of cooling decrements is similar to sum of decrements theorem for synchrotron radiation damping, i.e. decrement of longitudinal cooling can be split into appropriate portions to cool both transversely and longitudinally: J_s+J_h+J_v=1
- Vertical (better to say the second eigen mode) cooling is coming from transverse coupling

Non-achromatic chicane installed at the exit of the FEL before the kicker section turns the wave-fronts of the charged planes in electron beam

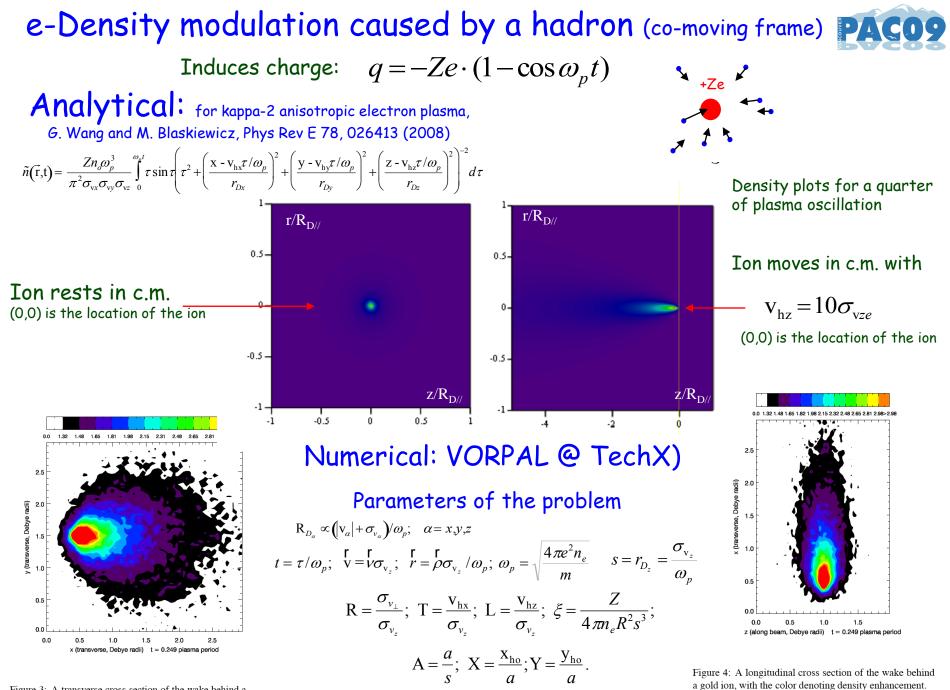

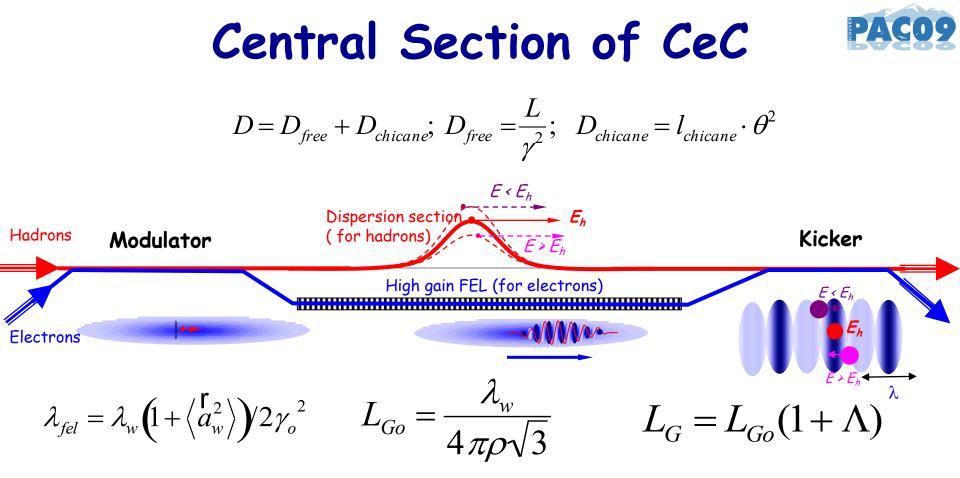

Figure 3: A transverse cross section of the wake behind a gold ion, with the color denoting density enhancement.

Electron density modulation is amplified in the FEL and made into a train with duration of $N_c \sim L_{gain}/\lambda_w$ alternating hills (high density) and valleys (low density) with period of FEL wavelength λ . Maximum gain for the electron density of High Gain FEL is ~ 10^{3} .

$$v_{group} = (c + 2v_{//})/3 = c \left(1 - \frac{1 + a_w^2}{3\gamma^2}\right) = c \left(1 - \frac{1}{2\gamma^2}\right) + \frac{c}{3\gamma^2} \left(1 - 2a_w^2\right) = v_{hadrons} + \frac{c}{3\gamma^2} \left(1 - 2a_w^2\right)$$

Economic option requires: $2a_w^2 < 1 \parallel \parallel$

Genesis: 3D FEL

Evolution of the maximum bunching in the e-beam and the FEL power simulated by Genesis. The location of the maxima, both for the optical power and the bunching progresses with a lower speed compared

with prediction by 1D theory, i.e. electrons carry ~75% for the "information" Evolution of the maxima locations in the e-beam bunching and the FEL power simulated by Genesis. Gain length for the optical power is 1 m (20 periods) and for the amplitude/modulation is 2m (40 periods)

$$\mathbf{v}_{g} \cong \frac{c + 3\left\langle \mathbf{v}_{z} \right\rangle}{4} = c \left(1 - \frac{3}{8} \frac{1 + a_{w}^{2}}{\gamma_{o}^{2}} \right)$$

©Y.Hao, V.Litvinenko

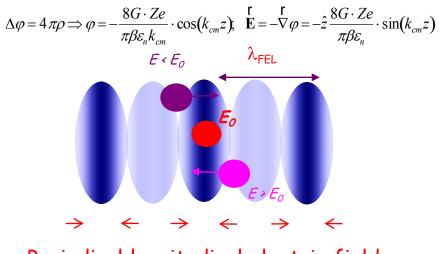

The Kicker

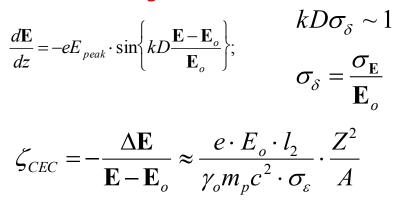

A hadron with central energy (E_o) phased with the hill where longitudinal electric field is zero, a hadron with higher energy ($E > E_o$) arrives earlier and is decelerated, while hadron with lower energy ($E < E_o$) arrives later and is accelerated by the collective field of electrons

Analytical estimation

Periodical longitudinal electric field

NATIONAL LABORATORY

Simulations: only started

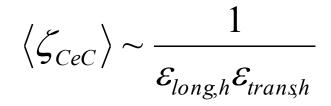

Step 1: use 3D FEL code out output + tracking First simulation indicate that equations on the left significantly underestimate the kick, i.e. the density modulation continues to grow after beam leaves the FEL -Bunching Bunching in the Kicker, 700 nm 0.6 **Output from** 0.5 Genesis propagated 0.4 for 25 m Bunching 0.3 0.2 ©I.Ben Zvi 0.1 0 10 25 0 15 20 Distance, m

Step 2: use VORPAL with input from Genesis, in preparation

Analytical formula for damping decrement

$$\left\langle \zeta_{CeC} \right\rangle = \zeta \frac{\sigma_{\tau,e}}{\sigma_{\tau,h}} = \kappa \cdot 2G_o \cdot \frac{Z^2}{A} \cdot \frac{r_p \cdot \sigma_{\tau,e}}{\varepsilon_{\perp n} \left(\sigma_{\delta} \cdot \sigma_{\tau,h} \right)}; \ \kappa \sim 1$$

Note that damping decrement

- a) Does not depend on the energy of particles !
- b) Improves as cooling goes on

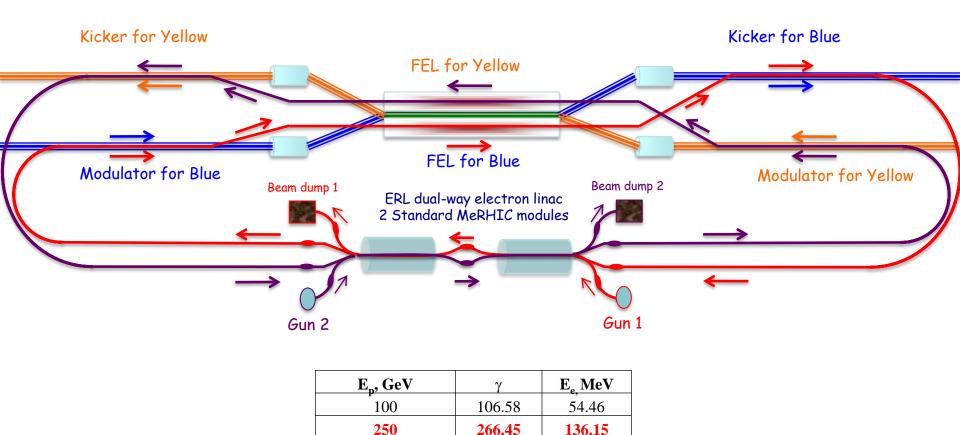

It makes it realistic to think about cooling intense proton beam in RHIC & LHC at 100s of GeV and 7 TeV energies Even though LHC needs one more trick (back up slides)

Possible layout in RHIC IP of CeC driven by a single linac -<u>to boost polarized pp- luminosity</u>

Example: CeC vs. IBS at RHIC

J.LeDuff, "Single and Multiple Touschek effects", Proceedings of CERN Accelerator School, Rhodes, Greece, 20 September - 1 October, 1993, Editor: S.Turner, CERN 95-06, 22 November 1995, Vol. II, p. 573

$$\frac{\sigma_{\varepsilon}^{2}}{\tau_{IBS\,I/}} = \frac{Nr_{c}^{2}c}{2^{5}\pi\gamma^{3}\varepsilon_{x}^{3/2}\sigma_{s}} \left\langle \frac{f(\chi_{m})}{\beta_{y}v} \right\rangle; \quad \frac{\varepsilon_{x}}{\tau_{IBS\,\perp}} = \frac{Nr_{c}^{2}c}{2^{5}\pi\gamma^{3}\varepsilon_{x}^{3/2}\sigma_{s}} \left\langle \frac{H}{\beta_{y}^{1/2}}f(\chi_{m}) \right\rangle; \\ \kappa = 1$$

$$f(\chi_{m}) = \int_{\chi_{m}}^{\infty} \frac{d\chi}{\chi} \ln\left(\frac{\chi}{\chi_{m}}\right) e^{-\chi}; \quad \chi_{m} = \frac{r_{c}m^{2}c^{4}}{b_{\max}\sigma_{E}^{-2}}; \quad b_{\max} \cong n^{-1/3}; \quad r_{c} = \frac{e^{2}}{mc^{2}}; \quad (e \to Ze; m \to Am)$$

IBS in RHIC for 250 GeV, N_p =210¹¹ were scaled from the data below Reference value was provided by A.Fedotov using Beta-cool code © Dubna

$$\varepsilon_{xn0} = 2 \,\mu m; \ \sigma_{s0} = 13 \ cm; \ \sigma_{\delta 0} = 4 \cdot 10^{-4}$$

 $\tau_{IBS\perp} = 4.6 \ hrs; \ \tau_{IBS//} = 1.6 \ hrs;$

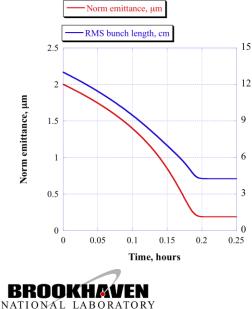

Stationary solution:

$$X = \frac{\tau_{CeC}}{\sqrt{\tau_{IBS}} \tau_{IBS}} \frac{1}{\sqrt{\xi_{\perp} (1 - 2\xi_{\perp})}}; \quad S = \frac{\tau_{CeC}}{\tau_{IBS}} \cdot \sqrt{\frac{\tau_{IBS}}{\tau_{IBS}}} \cdot \sqrt{\frac{\xi_{\perp}}{(1 - 2\xi_{\perp})^3}}$$
$$\varepsilon_{xn} = 0.2 \,\mu m; \ \sigma_s = 4.9 \ \text{cm}$$

This may allow RHIC pp - keep the luminosity at beam-beam limit all the time a) RHIC pp - reduce bunch length to few cm (from present 1 m) **b**) to reduce hourglass effect 1. To concentrate event in short vertexes of the detectors 2 c) eRHIC - reduce polarized beam current down to 50 mA while keeping the same luminosity eRHIC - increase electron beam energy to 20 GeV d) e) Both - increase luminosity by reducing β^* to 5-10 cm from present 0.5m

COHERENT ELECTRON COOLING 1. Physics of the method in general

Ya. S. Derbenev Randall Laboratory of Physics, University of Michigan Ann Arbor, Michigan 48109-1120 USA

CONCLUSION

The method considered above combines principles of electron and stochastic cooling and microwave amplification. Such an unification promises to frequently increase the cooling rate and stacking of high-temperature, intensive heavy particle beams. Certainly, for the whole understanding of new possibilities thorough theoretical study is required of all principle properties and other factors of the method.

V.N. Litvinenko, 2009 Particle Accelerator Conference, Vancouver, May 8, 2009

UM HE 91-28

Q: What's new in today's presentation?

- □ The spirit of amplifying the interaction remains the same as in 80's. but the underlying physics of interaction is different and also specific
- ERLs and FEL did advanced in last 30 years hence, the practicality of the scheme
- Now we can analytically estimate and numerically calculate CeC cooling decrements for a wide variety of cases

Potential increases in luminosities:

RHIC polarized pp ~ 2-4 fold, eRHIC ~ 5-10 fold, LHC ~ 2 fold

Start from longitudinal cooling , ultra-relativistic case (γ >>1)

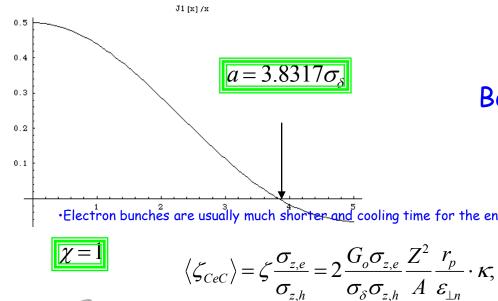

Analytical formula for damping decrement PASO 2

- 1/2 of plasma oscillation in the modulator creates a pancake of electrons with the charge -2Ze ٠
- electron clamp is well within $\Delta z \sim \lambda_{FFL} / 2\pi$
- gain in SASE FEL is $G \sim 10^2 10^3$
- electron beam is wider than $2\gamma_o\lambda_{FEL}$ it is 1D field
- Length of the kicker is ~ β -function

 $\delta = a \cdot \sin \Omega_{c} t$

$$\left\langle \delta^2 \right\rangle' = -\left\langle 2A \cdot a^2 \cdot \cos^2 \Omega_s t \cdot \sin \left(\frac{a}{\sigma_\delta} \cdot \chi \cdot \sin \Omega_s t \right) \right\rangle$$
$$= -2A \cdot \left\langle \delta^2 \right\rangle \cdot J_1 \left(\chi \cdot \frac{a}{\sigma_\delta} \right)$$

$$\zeta = -\frac{\Delta E_i}{E - E_o} = A \cdot \frac{L_2}{\beta} \cdot \chi \cdot \frac{\sin\varphi_3}{\varphi_3} \cdot \frac{\sin\varphi_2}{\varphi_2} \cdot \left(\sin\frac{\varphi_1}{2}\right)^2$$
$$A = 2G_o \frac{Z^2}{A} \cdot \frac{r_p}{\varepsilon_{\perp n} \sigma_\delta}; \quad \chi = k_{FEL} D \cdot \sigma_\delta;$$
$$\varphi_3 = k_{FEL} D\delta; \quad \delta = \frac{E - E_o}{E_o}$$

$$\frac{L_2}{\beta} \cdot \chi \cdot \operatorname{sinc}(\varphi_3) \cdot \operatorname{sinc} \varphi_2 \cdot \left(\sin \frac{\varphi_1}{2} \right)^2 \sim 1$$

 $\kappa \sim 1$

Beam-Average decrement

$$\int \frac{2J_1(x)}{x} e^{-x^2/2} dx = 0.889$$

•Electron bunches are usually much shorter and cooling time for the entire bunch is proportional to the bunch-lengths ratios

Effects of the surrounding particles PAS

Each charged particle causes generation of an electric field wave-packet proportional to its charge and synchronized with its initial position in the bunch

$$\mathbf{E}_{total}(\zeta) = \mathbf{E}_{o} \cdot \operatorname{Im}\left(X \cdot \sum_{i,hadrons} K(\zeta - \zeta_{i})e^{ik(\zeta - \zeta_{i})} - \sum_{j,electrons} K(\zeta - \zeta_{j})e^{ik(\zeta - \zeta_{j})}\right) \qquad \mathbf{E}_{o} = 2G_{o} \cdot \gamma_{o} \cdot \frac{e}{\beta\varepsilon_{\perp n}}$$
$$X = a/e \simeq Z(1 - \cos \varphi_{o}) \sim Z$$

Evolution of the RMS value resembles stochastic cooling! Best cooling rate achievable is ~ $1/N_{eff}$, N_{eff} is effective number of hadrons in coherent sample ($\Lambda_k = N_c \lambda$)

Fortunately, the bandwidth of FELs $\Delta f \sim 10^{13}$ - 10^{15} Hz is so large that this limitation does not play any practical role in most HE cases BROOKHAVEN

Conclusions

- Coherent electron cooling has potential of cooling high intensity TeV scale proton and ion beams with reasonable (under an hour) cooling time
- Electron accelerator of choice for such cooler is energy recovery linac (ERL)
- ERL seems to be capable of providing required beam quality for such coolers
- Majority of the technical limitation and requirements on the beam and magnets stability are well within limit of current technology, even though satisfying all of them in nontrivial fit
- We plan a proof of principle experiment of coherent electron cooling with Au ions in RHIC at ~ 40 GeV/n and existing R&D ERL as part of eRHIC R&D

Conclusions

- Coherent electron cooling is very promising method for significant luminosity increases in hadron colliders from RHIC to LHC
- Initial studies did not find any phenomena, which challenges the concept of CeC
- Our CeC estimations passed a number of tests
- At the same time, we found a number of new and interesting details to pursue further
- Future studies will refine the model and improve the quality of predictions
- We plan to test validity of the concept experimentally in Proof-of-Principle experiment using BNL's R&D ERL installed in one of available IPs at RHIC

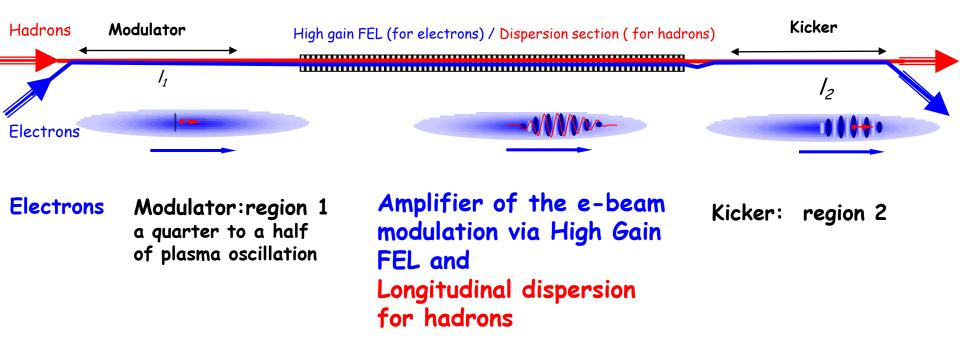

Supported by the Office on Nuclear Physics, US DoE

Coherent electron cooling, ultra-relativistic case ($\gamma > 1$)

Economic option

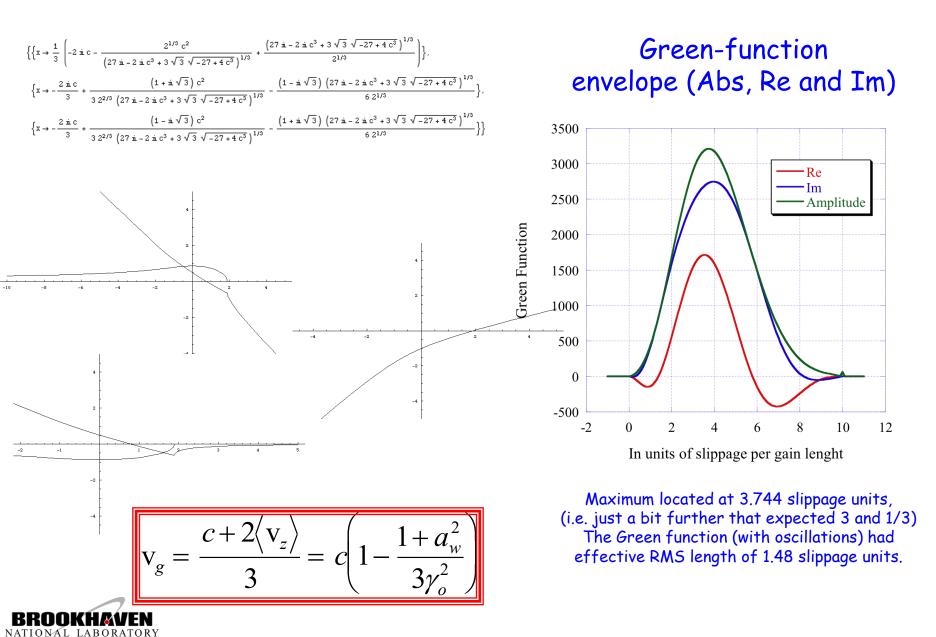

Electron density modulation is amplified in the FEL and made into a train with duration of $N_c \sim L_{gain}/\lambda_w$ alternating hills (high density) and valleys (low density) with period of FEL wavelength λ . Maximum gain for the electron density of HG FEL is ~ 10^{3} .

$$v_{group} = (c + 2v_{//})/3 = c \left(1 - \frac{1 + a_w^2}{3\gamma^2}\right) = c \left(1 - \frac{1}{2\gamma^2}\right) + \frac{c}{3\gamma^2} \left(1 - 2a_w^2\right) = v_{hadrons} + \frac{c}{3\gamma^2} \left(1 - 2a_w^2\right)$$

Economic option requires: $2a_w^2 < 1 \parallel \parallel$

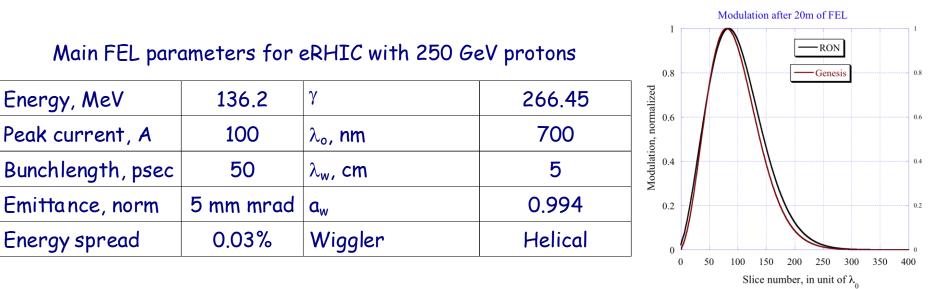

Response - 1D FEL after 10 gain length

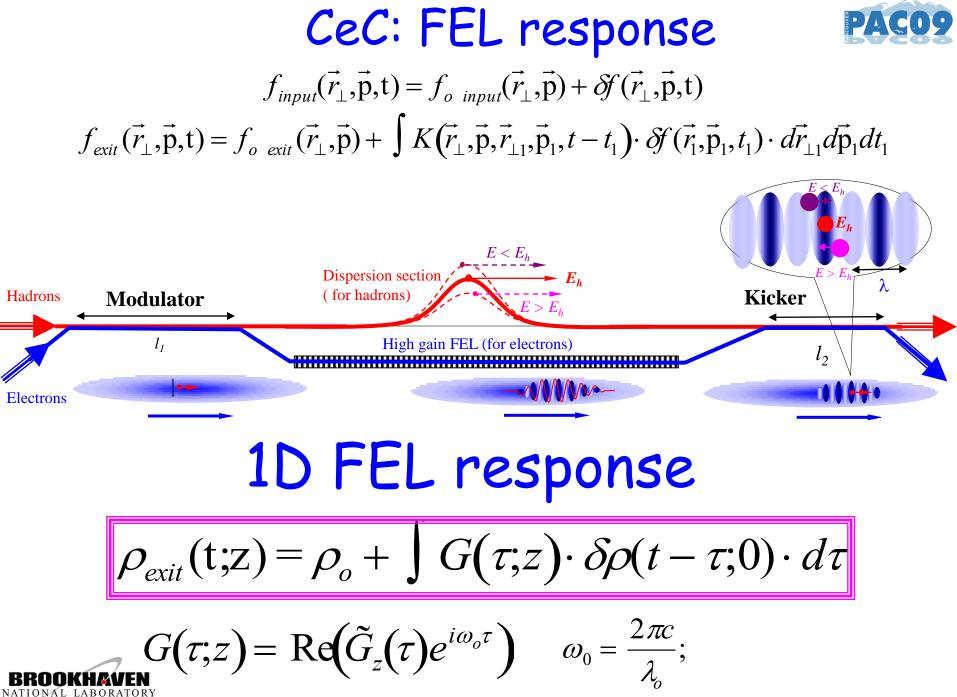

FEL's Green Function 1D - analytical approach $G(\tau;z) = \operatorname{Re}(\tilde{G}_{z}(\tau)e^{i\omega_{o}\tau})$ 3D - 3D FEL codes RON and Genesis 1.3

FEL parameters for Genesis 1.3 and RON simulations FEL gain length: 1 m (power), 2m (amplitude)

<u>Modulator</u>

Dimensionless equations of motion

+Ze

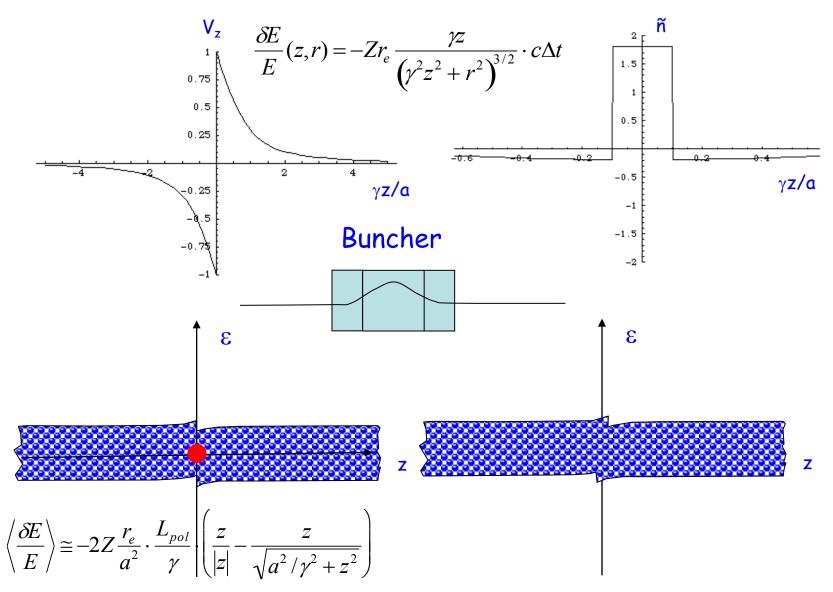

$$t = \tau/\omega_p; \quad \vec{v} = \vec{v}\sigma_{v_z}; \quad \vec{r} = \vec{\rho}\sigma_{v_z}/\omega_p; \quad \omega_p^2 = \frac{4\pi e^2 n_e}{m} \qquad S = r_{D_z} = \sigma_{v_z}/\omega_p$$

Parameters of the problem

$$\frac{\mathbf{R} = \frac{\sigma_{v_{\perp}}}{\sigma_{v_{z}}}; \ \mathbf{T} = \frac{\mathbf{v}_{\mathrm{hx}}}{\sigma_{v_{z}}}; \ \mathbf{L} = \frac{\mathbf{v}_{\mathrm{hz}}}{\sigma_{v_{z}}}; \ \boldsymbol{\xi} = \frac{Z}{4 \pi n_{e} R^{2} s^{3}}; \\ \mathbf{A} = \frac{a}{s}; \ \mathbf{X} = \frac{\mathbf{X}_{\mathrm{ho}}}{a}; \mathbf{Y} = \frac{\mathbf{y}_{\mathrm{ho}}}{a}.$$

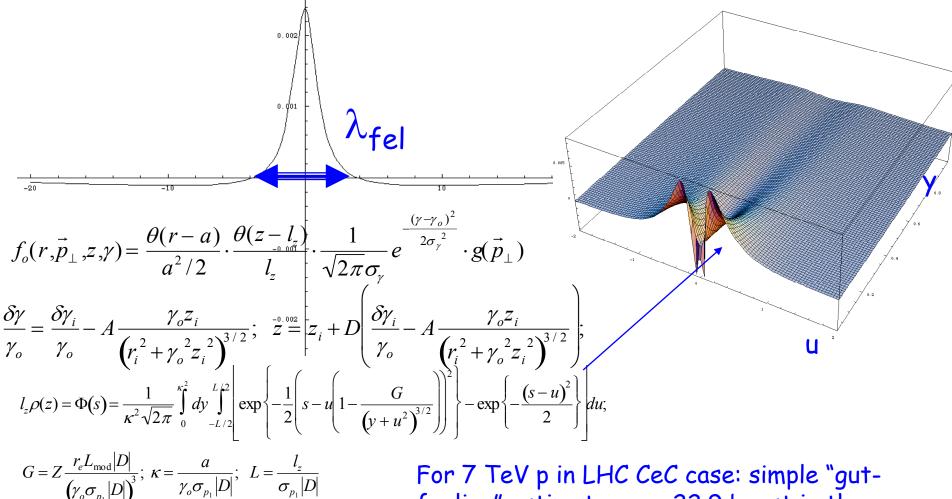

Velocity map & buncher (y>1000) PACOS

Exact calculations: solving Vlasov equation

 $u = \frac{x_1}{\sigma_{p_1}|D|}; \ s = \frac{z}{\sigma_{p_1}|D|}; \ y = \frac{r^2}{\left(\gamma_o \sigma_{p_1}|D|\right)^2}$

For 7 TeV p in LHC CeC case: simple "gutfeeling" estimate gave 22.9 boost in the induced charge by a buncher, while exact calculations gave 21.7.

<u>Comprehensive</u> studies

Analytical, Numerical and Computer Tools to:

1. find reaction (distortion of the distribution function of electrons) on a presence of moving hadron inside an electron beam

$$\frac{\partial f_e}{\partial t} + \frac{\partial f_e}{\partial \bar{v}} \cdot \frac{eE}{m} + \frac{\partial f_e}{\partial \bar{r}} \cdot \bar{v} = 0; \quad \vec{r}_h(t) \cong \vec{r}_o + \vec{v}_h t;$$

$$(\nabla \cdot \vec{E}) = 4 \pi e n_e \left(\frac{Z}{n_e} \delta(\vec{r} - \vec{r}_h(t)) - \int f_e d\vec{v}^3 \right).$$

$$f \Longrightarrow f_o + \delta f$$
