

Ronald Ransome

Thanks to Ronald Gilman  
for presenting this

Rutgers, The State University of New Jersey

- ◆ Safety considerations limit max activity to about 20 kCi
- ◆ High pressure (~225 psi) gas target is most likely candidate
- ◆ 40 cm long, 1.5 cm diameter cell with 80  $\mu\text{A}$  would give luminosity of  $\sim 3 \times 10^{36}/\text{cm}$
- ◆ Commercial uranium bed storage devices available
  - ◆ Cost in the \$50K-\$100K range
- ◆ Total cost likely in the few \$100K range
- ◆ Polarized target – many technical issues
  - ◆ Max current  $< 1 \mu\text{A}$ , few kCi – Don Crabb expert on this, will talk later in meeting

Workshop Sept. 1999 identified some feasible experiments with unpolarized target

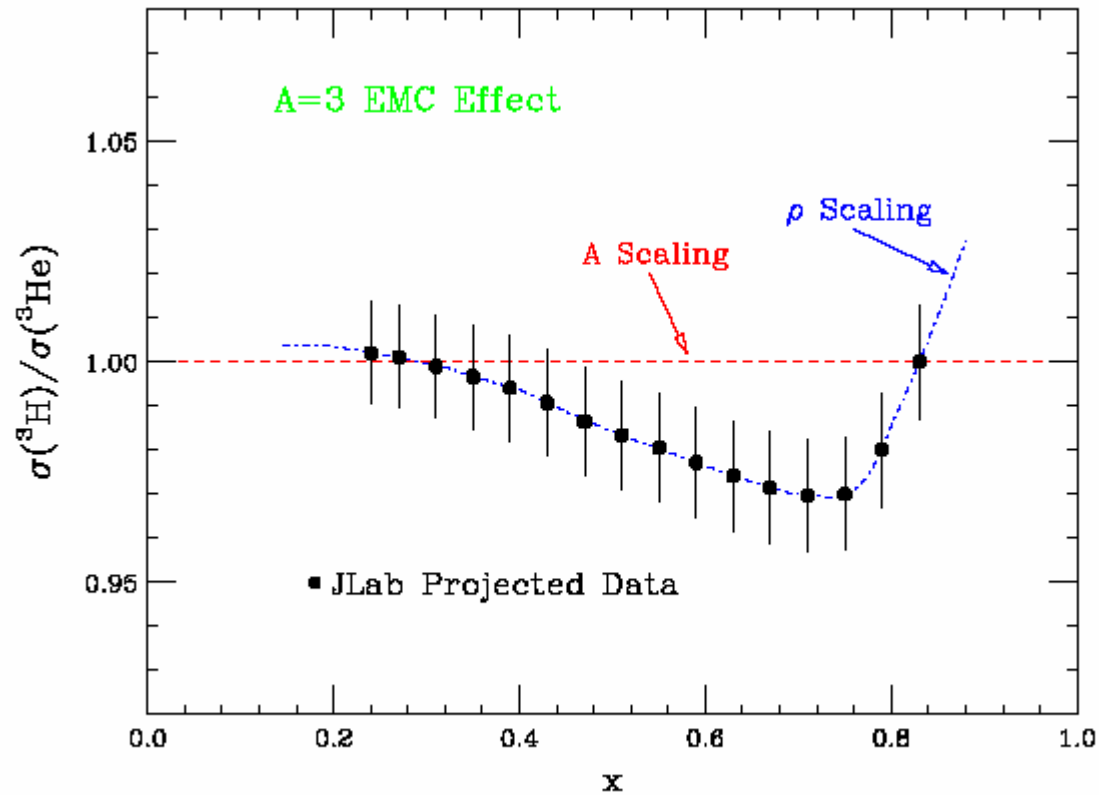

- ◆ Elastic form factors of  ${}^3\text{H}$
- ◆ u/d ratio
- ◆ EMC effect comparison of  ${}^3\text{H}$  and  ${}^3\text{He}$
- ◆ Coulomb sum
- ◆ Polarization transfer  ${}^3\text{H}(\vec{e}, e' \vec{p})$ 
  - ◆ Similar to  $G_E^n$ , compare extraction of proton form factor from  ${}^3\text{H}$  with neutron form factor from  ${}^3\text{He}$

u/d and EMC conditionally approved as PR-12-06-118 – Petratos, Gomez, Holt, Ransome, co-spokespersons

- ◆ Origins of EMC effect not completely understood
  - ◆ Preliminary JLab E03-103 results show significant EMC effect in  ${}^3\text{He}$  and that it is about the same in  ${}^4\text{He}$  and  ${}^{12}\text{C}$
  - ◆ Appears to be density dependent, based on latest JLab data
  - ◆ Precision comparison of  ${}^3\text{H}$  and  ${}^3\text{He}$  can help distinguish models – around 2% statistical precision possible for  $x$  up to about 0.8

# EMC in A=3

Projected data from PR-12-06-118

- ◆ u/d quark distribution function can be determined by comparison of  $^3\text{H}/^3\text{He}$  cross section ratio
- ◆ Extraction of u/d from deuteron depends on model for deuteron structure – major uncertainty at high  $x$

Projected data from PR-12-06-118

Yellow band indicates current uncertainty, mainly from deuteron wave function uncertainty

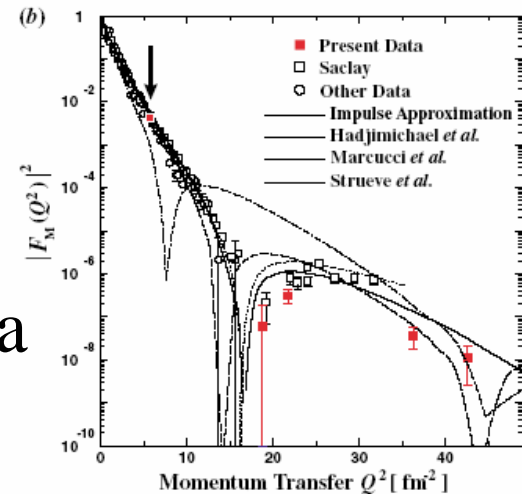

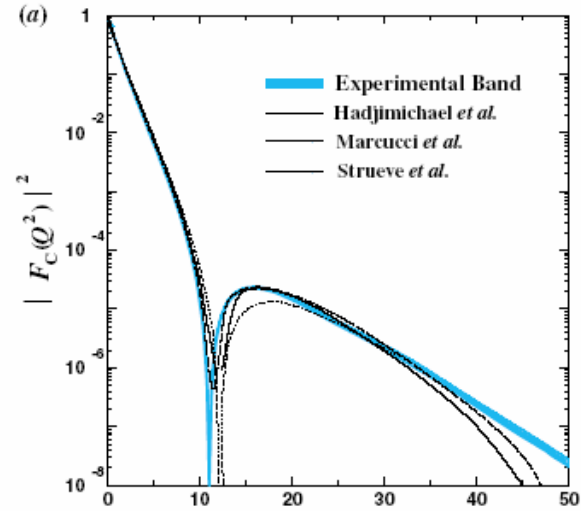

- ◆ Precision measurement of elastic form factors of light nuclei are essential test for nuclear models
  - ◆ Location of diffraction minimum can distinguish models
- ◆  $^3\text{He}$  well measured with recent Hall C data
  - ◆  $^3\text{He}$  known to  $Q^2 = 40 \text{ fm}^{-2}$  PRL **86**, 5446, (2001) Nakagawa et al.
  - ◆ Not well explained by current models
- ◆  $^3\text{H}$  needed for isospin dependence

$^3\text{H}$  poorly known for  $Q^2 > 16 \text{ fm}^{-2}$ , theoretical calculations from PRC 58, 3069 1998 Marucci, Riska, Schiavilla

JLab data on  $^3\text{He}$

- ◆ Requires  $\sim 5$  beam energies in 1-4 GeV range
- ◆ Could be measured in  $\sim 600$  hours with current Hall A spectrometers

- ◆ Provides information on correlations
- ◆ Sum defined as:

$$S_L(k) = \frac{1}{Z} \int_{\omega_{ai}^+}^{\infty} d\omega \frac{R_L(k, \omega)}{[G_{E,p}(k, \omega)]^2}$$

$$\begin{aligned} S_L(k) &= \frac{1}{Z} \langle 0 | \rho_L^\dagger(\mathbf{k}) \rho_L(\mathbf{k}) | 0 \rangle - \frac{1}{Z} |\langle 0 | \rho_L(\mathbf{k}) | 0 \rangle|^2 \\ &\equiv 1 + \rho_{LL}(k) - Z \frac{|F_L(k)|^2}{[G_{E,p}(k, \omega_{el})]^2} \end{aligned}$$

$\rho_{LL}$  is the proton-proton density

Coulomb sum being measured now in Hall A for nuclei  ${}^4\text{He}$ - ${}^{208}\text{Pb}$

Overall agreement with theory and experiment, but some discrepancies

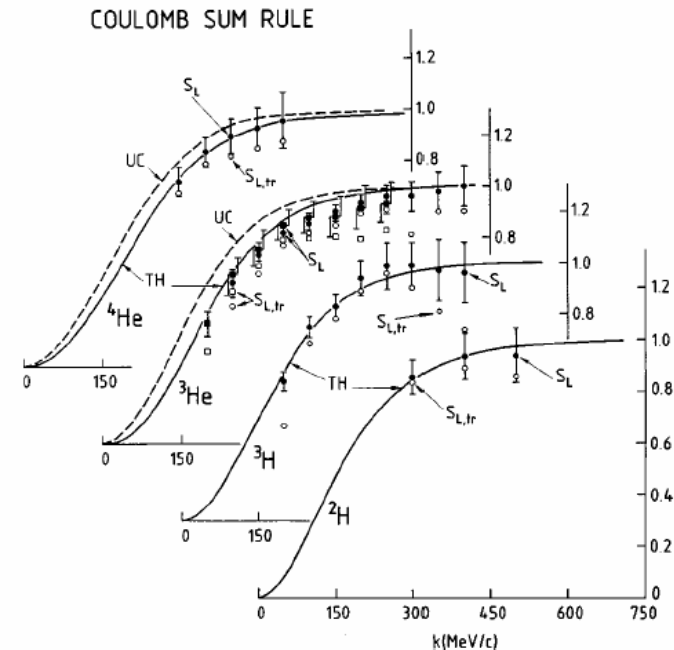

FIG. 45. The experimental  $S_{L,tr}$  (open data points) and tail-corrected  $S_L$  (filled data points with error bars) compared with theory in  ${}^2\text{H}$ ,  ${}^3\text{H}$ ,  ${}^3\text{He}$ , and  ${}^4\text{He}$ . Solid lines, Schiavilla, Pandharipande, and Fabrocini, 1989; dashed curves, the  $S_{L,unc}$  of  ${}^3\text{He}$  and  ${}^4\text{He}$ . Data for  ${}^3\text{He}$ : O, Saclay (Marchand *et al.*, 1985);  $\square$ , Bates (Dow *et al.*, 1988). Data for  ${}^2\text{H}$ : Bates (Dytman *et al.*, 1988). Data for  ${}^3\text{H}$ , Dow *et al.*, 1988; for  ${}^4\text{He}$  von Reden *et al.*, 1990.

# 3H, 3He Coulomb Sum

FIG. 1. Experimental and theoretical longitudinal-longitudinal distribution functions in  $^3\text{He}$ . Circles (squares) denote Bates (Saclay) data; solid symbols denote negative values. The curves labeled proton, 1-body, and full show theoretical results obtained from the Faddeev wave function by including in  $\rho_L$  the proton, one-body, and one- plus two-body contributions, respectively.

FIG. 3. Same as in Fig. 1 but for  $^3\text{H}$ .

Discrepancy between theory and experiment – need improved statistics and systematics

Figures from PRL 70, 3857, 1993 Schiavilla, Wiringa, Carlson  
 Data from PRL 64, 268, 1990 Beck et al.

- ◆ Could be measured in  $\sim 100$ - $200$  hours
- ◆ Requires several beam energies  $400 \text{ MeV} - 2 \text{ GeV}$

- ◆ Many interesting experiments with  $^3\text{H}$
- ◆ Target is technically feasible
- ◆ Coulomb sum, elastic form factor need lower beam energies
- ◆ u/d ratio, EMC effect best done with 12 GeV
  - ◆ Conditionally approved
